
BIG BOGS AND BATS

A deadly disease is killing millions of bats. Now Trump funding cuts threaten a promising Canadian treatment

At a crucial point in their research, biologists are scrambling to find new support for their study into a treatment for white-nose syndrome, a fungal disease that has devastated insect-eating bats across North America

Researchers Cal Lorsen and Mylene Mood step out of the warm spring sun and into a dusty lit workshop. The only light streams in through the doorway behind them and a few dusty windows. It's been a real start to the season in the Lower Mainland, but some bats have already been active for weeks. Mood and Lorsen are here to check on the progress of cousins to the critters of this wild, wood-building near Hayward Lake, about 90 kilometres east of Vancouver.

Mood, a field technician working with Lorsen, a bat biologist, flees a nook to the end of a wooden board and climbs up a ladder. As she scrapes the small black and fish boil below her, Lorsen peers into the nook. He's looking for signs of white-nose syndrome, a disease that, since May, circling the room below emitting back to meet. Lorsen offers a quiet apology. "Sorry, fellas." He collects the swab and deposits it into a vial. It will be tested for white-nose syndrome and sent to the wireless-sounding fungus behind a deadly disease called white-nose syndrome.

Over the past two decades, white-nose syndrome has killed millions of bats across North America. In the northeast it was, when the fungal disease was first detected, its toll is plain to see. Bats have been found dead in caves, in their hibernacula, and scientists have recorded a collective dying decimation. As the disease spread west, Lorsen, the director of bat conservation at Wildlife Conservation Society Canada, raced to find a solution.

Now, on the verge of confirming what could be a game-changing probiotic treatment for white-nose syndrome, Lorsen and his team face hurdles: U.S. President Donald Trump and his attack on federal government spending.

The new so-called Department of Government Efficiency, led by billionaire Elon Musk, slashed thousands of jobs and billions in funding from federal agencies, leaving a trail of bewildered organizations in January. The consequences have rippled well beyond U.S. borders. Lorsen's white-nose research was one of the Canadian projects affected. She was notified by the U.S. National Fish and Wildlife Foundation in January that her funding had been paused.

The second wave of bats is coming. Is Canada ready? — and for more on bats, check

This is a preview, but the grant applied for February. And although the organization has since reinstated the funding, Lorsen's team is still waiting for the money required to crucial next phase of study. Lorsen doesn't have much hope of success.

The funding debacle leaves Lorsen with a mix of emotions — excitement that early results are promising and panic that the Trump administration's funding cuts could unravel the whole project.

"It's like winning the World Cup, but not quite being able to score it," he says.

An 'ugly death': white-nose syndrome eats away at bats' skin as they hibernate

Bats are often misunderstood and maligned. They're seen as scary pests, linked with vampires and rabies, and feared as flying rodents that get tangled in hair. But bats are ecosystems — nighttime predators that help keep insect populations in check. They're important to their own right, but also to people. When bat populations decline, farmers can see increased crop damage and pesticide use, according to a 2011 study.

White-nose syndrome is the most destructive disease to hit North America. It takes hold during hibernation, the time of year when bats' defenses are weak. Thick bodies have cooled and their immune systems are powerful enough to fend off the cooperate envoys, giving Pseudogymnoascus destructans ample runway to develop into a disease that can be fatal. The fungus grows on bats' noses and wings, and as it grows, it eats away at their tissue. Each hibernation animal moves through the winter. As they groom the fungus from their wings, and their bodies warm up, their immune system turns back on, joining the battle against the fungus. Bats that survive the winter often emerge with large patches of skin of excavation before their lives feed at spring. "It's a pretty ugly death," Lorsen says.

Canada listed three bat species as endangered in 2014 after the disease caused populations to plummet in eastern provinces. Since then, white-nose syndrome has spread further west, including to British Columbia in 2023. The fungus has been detected in the province, but the disease, Lorsen says, has been unseen. Lorsen's team wanted to see it in the real world.

Lorsen knew it was only a matter of time before the fungus showed up in BC. She also knew treatments being tested in the east wouldn't work in the west. In the east, thousands of bats hibernate in single caves, but in BC, bats are more spread out, hibernating in small dispersed caves in the landscape, often in deep crevices or hollow underground.

It means the fungicides and other chemicals scientists spray on hibernating bats in the east aren't really an option here. But the large maternity caves, where bats breed in thousands of bats congregate over the spring and summer to birth and raise their babies, remain an opportunity.

Lorsen worked with scientists at Thompson Rivers and McMaster universities to develop the probiotic, a cocktail of beneficial bacteria — originally sourced from bats — that they hoped would give bats the boost they needed to fight off the fungus before it developed into the disease. Lab tests were promising, but Lorsen needed to test it in the real world.

Each spring and summer since 2019, her team has applied the probiotic to bat bones at maternity caves in the province. Each year, they've found more bats than the year before, hasn't yet been detected in the area. But the data is the best off-pile up enough of the probiotic as they seem to and all of the bones to keep the disease at bay, though hibernation if they do become infected.

Outside the workshop, Mood does a yellow poncho and a fresh pair of green lab gloves. She is ready to check the bat boxes that Lorsen and his team put up in the fall of 2023. In the past two years, the team has been using a modified bike pump to apply a mist of clay and probiotics to the bat boxes. It works, but it's messy, hence the ponchos.

Today Mood is trying out a new applicator on a tree line. She reaches each chamber of the box with water, as the mixture has something to stick to, then she puffs in the powder.

Even with the study at risk from Trump's funding cuts, the team is thinking about the best options for scaling up the treatment. The hope is that one day they'll be able to dip the bats themselves, rather than the bat boxes, which is a lot of travel time, time-around the continent to protect as many bats as possible.

This summer, she's excited to see if the probiotic has worked. Photo: Amelia Cavallaro-Smith / The Narwhal

Lorsen says the probiotic mix has shown up at control sites where the researchers were not applying the treatment. Those sites have had white-nose syndrome for years, and slightly more difficult to parse the results of their study, but she says it's ultimately good news.

If the probiotic proves effective at fighting off white-nose syndrome, it means the bats themselves can help redistribute the wealth of good bacteria — it's why Lorsen calls it's a "probiotic" rather than a "vaccine." Bats groom each other and share roosts in maternity colonies, eventually negating the need for frequent treatment. But without more definitive evidence the probiotic works, she worries they won't get the funding they'll need to go full-out.

Washington study sticks key to understanding probiotic's promise in white-nose syndrome fight: biologist

Lorsen's confident, though, that the compelling evidence the researchers need can be found across the border in Washington. In the past several years, bats have been found in mortality events attributed to white-nose syndrome documented in the state. About 100 bats have been found dead in caves — most of the same species, Lorsen says, that live in BC. The fungus has been detected, but biologists working with Lorsen have not yet found evidence the state for bats in the region, raising questions about how many are already dying caves.

For the past two years, Lorsen's been working with Tabitz to test the probiotic at three cave sites in Washington. Lorsen's team has been applying the probiotic treatment to bats in the nooks of Pseudogymnoascus destructans and, in some cases, to fungus at all. "Nothing has ever landed so positive with this science," Lorsen says.

Tabitz agrees. "It's helping with the microbiome on those wings for the better, so that's really promising and hopeful," she says in an interview.

But can probiotics definitively treat white-nose syndrome? The scientists need more time to find out.

"It's a very critical point in the study," Tabitz explains. While the preliminary results are encouraging, the disease is still in the early stages at all three sites. Tracking the problem's effect over the next two years as the disease develops could offer "pretty clear results," she says. They just need the money to do it.

One small saving grace is that white-nose syndrome seems to be spreading slightly slower in the west than it did in the east, Lorsen says. That's given her team a bit more time, but bats are dying during hibernation scattered out, because the strains are shorter, the fungus has less time to take hold before bats emerge in the spring better able to fight it off.

Another year of keeping a close watch

Here at The Narwhal, we don't use profit, awards or paperwork to measure success. The only thing that matters most is our readers' support — evidence that our independent, nonprofit reporting is known to uncover and pushed path-breakers to do better.

And in 2024, our stories were viewed in legislatures across the country and cited by citizens in their petitions and letters to politicians.

In Alberta, our reporting revealed Premier Danielle Smith made false statements about the province's environmental record. Our work also proved that officials failed to formally inspect a leaky pipeline for years. And our investigations as a funded recording of "Dr. Energy" executives were called "the most important Canadian political story of the year."

We'd like to thank you for paying attention. And if you're able to donate today, we'll be able to continue doing this work in 2025. Every dollar is worth a whole lot we can't predict — thank you so very much.

Will you help us build the powerful accountable in the year to come by giving what you can today?

Yes, I'll support independent journalism
